

**Listing of Claims:**

1. (Previously Presented) A magnetic field sensor, comprising:  
a sensor arrangement, which is supplied by a supply device and generates a sensor signal;  
an evaluation device, to which the sensor signal is fed and which outputs a first output signal corresponding to the amplitude of the sensor signal; and  
a feedback device, to which the first output signal is fed and which controls the supply device such that the first output signal remains substantially constant.

2. (Previously Presented) The magnetic field sensor as claimed in claim 1, wherein the sensor arrangement contains a Hall element arrangement, which is fed by a Hall current and generates a Hall signal as sensor signal, and comprising a feedback device embodied as an amplification device, to which the first output signal is fed and which controls the Hall current.

3. (Previously Presented) The magnetic field sensor as claimed in claim 1, wherein the first output signal corresponds to the actual value amplitude of the sensor signal and the feedback device sets the supply device with the aid of a predetermined desired value amplitude such that the amplitude of the sensor signal remains constant.

4. (Previously Presented) The magnetic field sensor as claimed claim 2, wherein the Hall element arrangement detects a rotating magnetic field and a second output signal of the evaluation device corresponds to the rotation angle determined.

5. (Previously Presented) The magnetic field sensor as claimed in claim 2, wherein the Hall signal of the Hall element arrangement contains a first measurement signal and a second measurement signal, which is phase-shifted by  $90^\circ$  relative to the first measurement signal.

6. (Previously Presented) The magnetic field sensor as claimed in claim 1, wherein the evaluation device contains an analog-to-digital converter, which digitizes the sensor signal, and a computation device connected downstream, which generates the first and/or the second output signal.

7. (Previously Presented) The magnetic field sensor as claimed in claim 1, wherein the feedback device contains a comparator (K), which compares the first output signal with a reference value, in that a counter is connected downstream of the comparator, the output signal of the comparator being fed to said counter, and in that a digital-to-analog converter is connected downstream of the counter, and converts the output signal of the counter into a control signal for the supply device.

8. (Previously Presented) A method for the operation of a magnetic field sensor comprising:

supplying with a supply device a sensor element of the magnetic field sensor; and

generating with the sensor element a sensor signal that is conditioned by means of an evaluation device to form a first output signal corresponding to the amplitude of the sensor signal, and feeding the sensor signal to a feedback device, which controls the supply device on the output side such that the first output signal remains constant.

9. (Previously Presented) The method as claimed in claim 8, wherein the actual value amplitude of the sensor signal is derived from the first output signal and the feedback device sets the supply device with the aid of a predetermined desired value amplitude such that the actual value amplitude of the sensor signal remains constant.

10. (Previously Presented) The method as claimed in claim 8, wherein a rotating magnetic field is detected by means of the sensor element and a second output signal corresponding to the rotation angle is generated by means of the evaluation device.

11. (Previously Presented) The method as claimed in claim 8, wherein a sensor element embodied as a Hall element arrangement is arranged in such a way that the Hall signal contains a first measurement signal and a second measurement signal, which is phase-shifted by 90° relative to the first measurement signal.

12. (Previously Presented) The method as claimed in claim 8, wherein the evaluation device digitizes the sensor signal by means of an analog-to-digital converter, and a computation device connected downstream of the evaluation device generates the first and/or the second output signal.

13. (Previously Presented) The method as claimed in claim 8, wherein the first output signal is compared with a reference value in a comparator, in that a counter connected downstream of the comparator derives a count from the output signal of the comparator and a

digital-to-analog converter converts the output signal of the counter into a control signal for the supply device.
